Q1) Create two tables: AppOrders (for orders placed via a food delivery app like Zomato) and InStoreOrders (for direct restaurant orders), each with columns: order_id, customer_name, amount, and order_date. Insert at least 3 sample records into each table.

```sql
SELECT * FROM AppOrders;

SELECT * FROM
InStoreOrders;
```

Q2) Write a SQL query using UNION to combine all unique customer names from both AppOrders and InStoreOrders tables into a single list.

```sql
SELECT customer_name
FROM AppOrders

UNION

SELECT customer_name
FROM InStoreOrders;
```

Q3) Write a SQL query using UNION ALL to display every order (including duplicates if any) from both AppOrders and InStoreOrders, showing order_id, customer_name, amount, and order_date.

```sql
SELECT order_id,
customer_name, amount,
order_date
FROM AppOrders

UNION ALL

SELECT order_id,
customer_name, amount,
order_date
FROM InStoreOrders;
```

Q4) Demonstrate the difference between UNION and UNION ALL by adding a duplicate customer_name in both tables, then running both queries and noting the difference in the result count.

Hint: UNION removes duplicates, UNION ALL does not.

UNION

```
SELECT customer_name
FROM AppOrders

UNION

SELECT customer_name
FROM InStoreOrders;

-- Removes Duplicate
rows.
-- Returns only unique
records.
```

UNION ALL

```
SELECT customer_name FROM
AppOrders

UNION ALL

SELECT customer_name FROM
InStoreOrders;

-- Keeps Duplicate rows.
-- Returns All records.
```
